# Miniproject - Analytic Number Theory

#### Simon Pohmann

We use the convention that  $\mathbb{N} = \{n \in \mathbb{Z} \mid n \geq 0\}$ . Further, we write  $a \mid b$  if a divides b and  $a \perp b$  if a and b are coprime. Finally, let  $\mathbb{P}$  be the set of prime numbers in  $\mathbb{N}$ .

## 1 Part I

For convenience, we include the definition of a Dirichlet character from the task description first.

**Definition 1.** Let  $q \geq 2$ , then a Dirichlet character (mod q) is a function  $\chi : \mathbb{N} \to \mathbb{C}$  such that

- $\chi$  is completely multiplicative, so  $\chi(a)\chi(b) = \chi(ab)$
- $\chi$  is periodic modulo q, so  $\chi(n+q) = \chi(n)$
- $\chi(n) \neq 0$  if and only if  $n \perp q$

First, we will give another characterization of Dirichlet characters.

**Lemma 2** (Characterization of Dirichlet characters). We have a one-to-one correspondence between Dirichlet characters mod q and group homomorphisms  $(\mathbb{Z}/q\mathbb{Z})^{\times} \to \mathbb{C}^{\times}$  via

$$\{f: (\mathbb{Z}/q\mathbb{Z})^{\times} \to \mathbb{C}^{\times} \mid f \text{ group hom}\} \to \{\chi: \mathbb{N} \to \mathbb{C} \mid \chi \text{ Dirichlet character mod } q\}$$
$$f \mapsto \chi_f := \left(\mathbb{N} \to \mathbb{C}, \ n \mapsto \begin{cases} f([n]) & \text{if } n \perp q \\ 0 & \text{otherwise} \end{cases}\right)$$

*Proof.* First of all, we show that the map is well-defined. Let  $f: (\mathbb{Z}/q\mathbb{Z})^{\times} \to \mathbb{C}^{\times}$  be a (multiplicative) group homomorphism, and we show that  $\chi_f$  is a Dirichlet character.

Note that property (ii) and (iii) directly follow from the definition, as  $\chi_f(n)$  only depends on the value of  $n \mod q$ . So consider some  $a, b \in \mathbb{N}$ . If both  $a \perp q$  and  $b \perp q$  then

$$\chi_f(a)\chi_f(b) = \chi([a])\chi([b]) = \chi([ab]) = \chi_f(ab)$$

as also  $ab \perp q$ .

On the other hand, if  $a \not\perp q$  or  $b \not\perp q$  have  $\chi_f(a) = 0$  resp.  $\chi_f(b) = 0$ . We also have in this case that  $ab \not\perp q$  and so

$$\chi_f(a)\chi_f(b) = 0 = \chi_f(ab)$$

Now it is left to show that the correspondence is a bijection. Clearly, if  $f \neq g$  then  $f(x) \neq g(x)$  for some  $x \in (\mathbb{Z}/q\mathbb{Z})^{\times}$  and so  $\chi_f(n) \neq \chi_g(n)$  for some representative  $n \in \mathbb{N}$  of x.

To show surjectivity, consider some Dirichlet character  $\chi: \mathbb{N} \to \mathbb{C}$  and construct a group homomorphism  $f: (\mathbb{Z}/q\mathbb{Z})^{\times} \to \mathbb{C}^{\times}$ . For each  $x \in (\mathbb{Z}/q\mathbb{Z})^{\times}$ , there is a representative  $n \in \mathbb{N}$  of x and as  $\chi(n)$  does not depend on the choice of n, we may define  $f(x) := \chi(n)$ . Note that as  $x \in (\mathbb{Z}/q\mathbb{Z})^{\times}$ , we find  $n \perp q$  and so  $\chi(n) \neq 0$ , i.e.  $\chi(n) \in \mathbb{C}^*$ . Then clearly for  $a, b \in (\mathbb{Z}/q\mathbb{Z})^*$  with representatives  $n, m \in \mathbb{N}$  have

$$f(ab) = \chi(nm) = \chi(n)\chi(m) = f(a)f(b)$$

So f is a well-defined group homomorphism and we obviously have  $\chi_f = \chi$ .

For simplicity of notation we sometimes will identify a Dirichlet character and its group homomorphism if it is always clear which one is meant.

Example 3 (Ex (i)). The function

$$f: \mathbb{N} \to \mathbb{C}, \quad n \mapsto \begin{cases} 0 & \text{if } n \equiv 0, 2 \mod 4 \\ 1 & \text{if } n \equiv 1 \mod 4 \\ -1 & \text{if } n \equiv 3 \mod 4 \end{cases}$$

is a Dirichlet character.

*Proof.* This follows directly from Lemma 2, as  $f = \chi_q$  for the group homomorphism

$$q: (\mathbb{Z}/4\mathbb{Z})^{\times} = \{1,3\} \to \mathbb{C}^*, \quad 1 \mapsto 1, 3 \mapsto -1$$

(this is a group homomorphism, as  $3^2 = 9 \equiv 1 \mod 4$ )

Now we want to define Dirichlet series of Dirichlet characters.

**Proposition 4.** For a Dirichlet character  $\chi: \mathbb{N} \to \mathbb{C}$  and some  $\epsilon > 0$ , the series

$$L(s,\chi) := \sum_{n \ge 1} \chi(n) n^{-s}$$

converges uniformly on  $\Re(s) \geq 1 + \epsilon$ . We will call it the Dirichlet series of  $\chi$ .

*Proof.* By Lemma 2, we know that  $\chi$  corresponds to a group homomorphism  $f: (\mathbb{Z}/q\mathbb{Z})^{\times} \to \mathbb{C}^{\times}$  such that  $\chi(\mathbb{N}) = f((\mathbb{Z}/q\mathbb{Z})^*) \cup \{0\} \subseteq \mathbb{C}$  is a finite subset of  $\mathbb{C}$ . Hence, there is C > 0 with  $|\chi(n)| \leq C$  for all  $n \in \mathbb{N}$ , and it follows that

$$\sum_{1 \leq n \leq X} \left| \chi(n) n^{-s} \right| \leq \sum_{1 \leq n \leq X} C \left| n^{-s} \right| \leq C \sum_{1 \leq n \leq X} n^{-1 - \epsilon} \leq C \sum_{n \geq 1} n^{-1 - \epsilon}$$

which is finite.  $\Box$ 

**Proposition 5.** Let  $f:(\mathbb{Z}/q\mathbb{Z})^{\times}\to\mathbb{C}^{\times}$  be a group homomorphism. Then for the associated Dirichlet character  $\chi=\chi_f$  we have that

$$\lim_{s \to 1^+} L(s, \chi) \text{ exists } \Leftrightarrow \sum_{x \in (\mathbb{Z}/q\mathbb{Z})^{\times}} f(x) = 0$$

If this is the case, then

$$\lim_{s \to 1^+} L(s, \chi) = \sum_{n > 1} \frac{\chi(n)}{n}$$

where the right-hand side converges (but not absolutely).

*Proof.* Let  $c = \sum_{x \in (\mathbb{Z}/q\mathbb{Z})^{\times}} f(x)$ . For the direction  $\Rightarrow$  assume that  $c \neq 0$ . Then have for  $\Re(s) > 1$  that

$$sgn(c) \sum_{n \ge 1} \chi(n) n^{-s} = \sum_{n \ge 0} \sum_{0 < k \le q} sgn(c) \chi(qn+k) (qn+k)^{-s}$$

$$\ge \sum_{n \ge 0} \sum_{0 < k \le q} sgn(c) \chi(qn+k) (qn+n)^{-s}$$

$$= \sum_{n \ge 0} sgn(c) (qn+n)^{-s} \sum_{0 < k \le q} \chi(qn+k)$$

$$\ge \frac{|c|}{(q+1)^s} \sum_{n \ge 1} n^{-s} = \frac{|c|}{(q+1)^s} \zeta(s)$$

which clearly has a pole at s=1. Hence  $\lim_{s\to 1^+} L(s,\chi_f)$  cannot exist.

For the other direction, assume that c = 0. We will only consider real s now. Observe that by Bernoulli's inequality, have for  $0 < s \le 1$  that

$$(qn)^{-s} - (qn+k)^{-s} = \frac{(qn+k)^s - (qn)^s}{(q^2n^2 + qnk)^s} = (qn)^s \frac{(1+k(qn)^{-1})^s - 1}{(q^2n^2 + qnk)^s}$$

$$\leq (qn)^s \frac{sk(qn)^{-1}}{(q^2n^2 + qnk)^s} = \frac{sk}{qn(qn+k)^s} = O(sn^{-s-1})$$

If s > 1 and  $k \le q$ , then also  $(qn)^{-s} - (qn + k)^{-s} = O(sn^{-(1+\epsilon)})$  for some small enough  $0 < \epsilon < 1$ . As  $\chi((\mathbb{Z}/q\mathbb{Z})^{\times}) \subseteq \mathbb{C}$  is finite, find C > 0 with  $|\chi_f(n)| \le C$  for all  $n \in \mathbb{N}$ .

Then for all  $s \geq \epsilon$  and  $X \leq Y$  it holds

$$\begin{split} &\sum_{X \leq n \leq Y} \chi(n) n^{-s} \\ &= O(qCX^{-s} + qCY^{-s}) + \sum_{X/q \leq n \leq Y/q} \sum_{0 < k \leq q} \chi(qn+k) \Big( (qn)^{-s} + \underbrace{(qn+k)^{-s} - (qn)^{-s}}_{=O(sn^{-(1+\epsilon)})} \Big) \\ &= O(qCX^{-s}) + \sum_{X/q \leq n \leq Y/q} \Big( (qn)^{-s} c + \sum_{0 < k \leq q} O(Csn^{-(1+\epsilon)}) \Big) = \\ &= O(qCX^{-s}) + 0 + O\Big( Cqs \sum_{X/q \leq n \leq Y/q} n^{-(1+\epsilon)} \Big) \\ &= O(qCX^{-s}) + O\Big( Cqs \sum_{X/q \leq n} n^{-(1+\epsilon)} \Big) \end{split}$$

which is well-defined and finite. Further, the expression converges uniformly (as a function in s on  $[\epsilon, \infty[)$  to 0 as  $X \to \infty$ . So

$$\sum_{n < X} \chi(n) n^{-s} \quad \text{converges uniformly to} \quad \sum_{n > 1} \chi(n) n^{-s}$$

as  $X \to \infty$  (on  $[\epsilon, \infty[$ ). Thus the limit is continuous and extends  $L(s, \chi_f)$  defined on  $]1, \infty[$ . It follows that  $\lim_{t\to s^+} L(t, \chi_f)$  exists and is equal to  $\sum_{n\geq 1} \chi(n) n^{-s}$ .

Applied to our example, we find

**Example 6** (Ex (ii)). Let  $f: \mathbb{N} \to \mathbb{C}$  be the Dirichlet character from Example 3 with corresponding group homomorphism  $g: (\mathbb{Z}/4\mathbb{Z})^{\times} \to \mathbb{C}$ . Then

$$\sum_{x \in (\mathbb{Z}/4\mathbb{Z})^*} g(x) = g(1) + g(3) = 1 - 1 = 0$$

and so by Lemma 5 the limit  $\lim_{s\to 1^+} L(s,f)$  exists. The lemma further yields that

$$\lim_{s \to 1} L(s, f) = \sum_{n \ge 1} f(n)n^{-1} = \sum_{n \ge 0} \frac{f(4n+1)}{4n+1} + \frac{f(4n+3)}{4n+3} = \sum_{n \ge 0} \frac{1}{4n+1} - \frac{1}{4n+3}$$
$$= 2\sum_{n \ge 0} \frac{1}{(4n+1)(4n+3)} > 0$$

is positive. Wolfram Alpha [Inc] can give an explicit value to this sum, using the digamma function  $\psi$ . Namely

$$\sum_{x \in (\mathbb{Z}/4\mathbb{Z})^{\times}} f(n)n^{-1} = \frac{1}{4}(\psi(\frac{7}{4}) - \psi(\frac{5}{4}))$$

which seems to be  $\frac{1}{4}$ .

Now we want to study the series

$$\sum_{p} f(p)p^{-s}$$

For this, we are first interested in how many primes  $\equiv 1, 3 \mod 4$  there are.

**Lemma 7.** Let  $n \equiv 3 \mod 4$ . Then n has a prime factor  $p \equiv 3 \mod 4$ .

*Proof.* Use induction on n. If n=3, the claim is trivial. So let n>3. If n is prime, the claim again follows. Otherwise, have n=ab with nontrivial divisors a,b. However,  $3 \equiv n$  is not a square modulo 4, so find that  $a \not\equiv b \mod 4$ . As both a and b must be odd, we see that either  $a \equiv 3 \mod 4$  or  $b \equiv 3 \mod 4$  and the claim follows by the induction hypothesis.

Corollary 8 (Ex (iii)). There are infinitely many primes p with  $p \equiv 3 \mod 4$ .

*Proof.* Assume there were only finitely many, say  $p_1, ..., p_N$ . Let  $P := p_1...p_N$  if N is even and  $P := p_1^2 p_2...p_N$  if N is odd. Then

$$P \equiv 3^{2\lceil \frac{N}{2} \rceil} \equiv 1^{\lceil \frac{N}{2} \rceil} = 1 \mod 4$$

Thus, by Lemma 7, P+2 has a prime factor  $q \equiv 3 \mod 4$ . However,  $q \neq p_i$  as  $p_i \perp P+2$  for all i (if  $p_i \mid P+2$ , then  $p_i \mid P+2-P=2$ , a contradiction). This contradicts our assumption.

For the case of primes  $\equiv 1 \mod 4$ , I have remembered the two-square theorem and its connection to primes in the ring  $\mathbb{Z}[i]$  of Gaussian integers, and somehow my train of thoughts went into Algebraic Number Theory. After some research, I have found an exercise in [Neu92, Chapter I, §10] that requires the reader to prove the following proposition.

**Proposition 9.** Let  $q \ge 3$  be an integer. Then there are infinitely many primes p with  $p \equiv 1 \mod q$ .

*Proof.* Assume there were only finitely many such primes  $p_i$ , then we have their product  $P = \prod_i p_i \in \mathbb{Z}$ . Consider now the q-th cyclotomic polynomial  $\Phi_q$ . Clearly  $\Phi_q(qPX) - 1 \in \mathbb{Q}[X]$  has at most  $\phi(q)$  zeros, so there exists some  $x \in \mathbb{Z}$  with  $\Phi_q(qPx) \neq 1$  (this "Ansatz" was given as a hint).

Let now  $K = \mathbb{Q}(\omega_q)$  be the q-th cyclotomic number field with a primitive q-th root of unity  $\omega_q$  (i.e.  $\Phi_q(\omega_q) = 0$ ). Let further  $\mathcal{O} \subseteq K$  be the ring of integral elements over  $\mathbb{Z}$  in K. The prime decomposition law for Dedekind ring extension [Neu92, Chapter I, Prop 8.3] tells us that for a prime p, the ideal (p) is reducible in  $\mathcal{O}$  if and only if  $\Phi_q \mod p$  is reducible. As  $(\mathbb{Z}/p\mathbb{Z})^{\times}$  is cyclic of order p-1, this is the case if and only if  $q \mid p-1$ , i.e.  $p \equiv 1 \mod q$ .

Now consider the element  $\alpha = \omega_q - xqP \in \mathcal{O}$ . Then

$$N_{K/\mathbb{Q}}(\alpha) = \prod_{\sigma: K \to \mathbb{C} \text{ } \mathbb{Q}\text{-field homomorphism}} \sigma(\omega_q - xqP)$$
$$= \prod_{\sigma} (\sigma(\omega_q) - xqP) = \text{MiPo}_{\mathbb{Q}}(\omega_q)(xqP) = \Phi_q(xqP) \neq 1$$

as  $\operatorname{MiPo}_{\mathbb{Q}}(\omega_q) = \prod_{\sigma} (\sigma(\omega_q) - X)$ . Hence,  $\alpha$  is not a unit in  $\mathcal{O}$ . On the other hand,  $(\alpha)$  is coprime to  $(p_i)$  for each  $p_i$ , as

$$\omega_q = \alpha - xqP \in (\alpha) + (p_i)$$
 and  $\omega_q \in \mathcal{O}^{\times}$ 

By our assumption, the only prime ideals in  $\mathcal{O}$  are the prime ideal factors of  $(p_i)$  and (p) for  $p \neq p_i$ . Thus, the prime ideal factorization of  $(\alpha)$  consists only of prime ideals  $(p), p \neq p_i$  and it follows that  $(\alpha) = (n)$  for some integer  $n \geq 2$ . As  $\omega_q$  and  $xqP \in \mathbb{Z}$  are  $\mathbb{Q}$ -linearly independent, we see that  $n \mid \omega_q$  and  $n \mid xqP$ . However, the former is a contradiction, as  $\omega_q \in \mathcal{O}^{\times}$  is a unit and no  $n \geq 2$  is a unit.

The book also mentions that the general case can be proven by using L-series in algebraic number fields.

Corollary 10 (Ex (iii)). There are infinitely many primes p with  $p \equiv 1 \mod 4$ .

*Proof.* This is just a special case of Prop. 9.

**Example 11** (Ex (iii)). Using a computer, we can also study the actual frequency of prime numbers  $\equiv 1,3 \mod 4$  among e.g. the first  $10^8$  integers. This seems to indicate that both numbers are asymptotically equal. For example, there are 332180 primes  $\equiv 1 \mod 4$  and 332398 primes  $\equiv 3 \mod 4$  smaller than  $10^8$ . To find these numbers, the following python code was used.

```
import math

def primes():
    yield 2
    found_primes = [2]
    for n in itertools.count(3):
        for p in found_primes:
            if n % p == 0:
                break
        elif p >= math.sqrt(n):
                yield n
                found_primes.append(n)
                break
```

**def** primes leq(n):

import itertools

```
return itertools.takewhile(lambda p: p <= n, primes())
```

#### 2 Part II

We have already shown that Dirichlet characters are, in principle, group homomorphisms  $(\mathbb{Z}/q\mathbb{Z})^{\times} \to \mathbb{C}^{\times}$ . If we now assume q to be prime, we get an even nicer characterization. So for the whole section, assume that  $q \geq 3$  is a prime.

**Corollary 12** (Ex (i)). Let  $\chi, \chi' : \mathbb{N} \to \mathbb{C}$  be Dirichlet characters mod q and r a representative of a primitive root modulo q. If  $\chi(r) = \chi'(r)$ , then  $\chi = \chi'$ . Further, have that  $\chi(n)^{q-1} = 1$  for all  $n \in \mathbb{N}$  with  $n \perp q$ .

*Proof.* The properties follow directly from Lemma 2. Let  $f, f' : (\mathbb{Z}/q\mathbb{Z})^{\times} \to \mathbb{C}^{\times}$  be the associated group homomorphisms of  $\chi, \chi'$  as in Lemma 2. If  $f([r]) = \chi(r) = \chi'(r) = f'([r])$  then clearly f = f', as these are group homomorphisms and  $\langle [r] \rangle = (\mathbb{Z}/q\mathbb{Z})^{\times}$ . Hence  $\chi = \chi'$ .

Further, have for  $n \in \mathbb{N}$  with  $n \perp q$  that  $[n] \in (\mathbb{Z}/q\mathbb{Z})^{\times}$  and thus

$$[n]^{q-1} = [n]^{\phi(q)} = [n]^{|(\mathbb{Z}/q\mathbb{Z})^{\times}|} = 1$$

As f is a group homomorphism, find

$$\chi(n)^{q-1} = f([n])^{q-1} = f([n]^{q-1}) = f(1) = 1$$

This correspondence also works in the other direction.

Corollary 13 (Ex (ii)). Let  $\omega \in \mathbb{C}$  be a (q-1)-th root of unity, i.e.  $\omega^{q-1} = 1$  and let  $r \in \mathbb{Z}$  be a representative of a primitive root modulo q. Then

$$g: \mathbb{N} \to \mathbb{C}, \quad n \mapsto \begin{cases} \omega^{\log_r n} & \text{if } n \perp q \\ 0 & \text{otherwise} \end{cases}$$

is a well-defined Dirichlet character.

*Proof.* Follows again directly from Lemma 2, as  $[r] \mapsto \omega$  induces a unique group homomorphism  $(\mathbb{Z}/q\mathbb{Z})^{\times} \to \mathbb{C}^{\times}$ . The associated Dirichlet character is obviously g.

Note that the image of a group homomorphism  $f:(\mathbb{Z}/q\mathbb{Z})^{\times}\to\mathbb{C}^{\times}$  is a subgroup of  $\mathbb{C}^{\times}$ . Using Corollary 12, we can describe it quite concretely.

**Proposition 14.** Let  $\chi : \mathbb{N} \to \mathbb{C}$  be a Dirichlet character with group homomorphism  $f : (\mathbb{Z}/q\mathbb{Z})^{\times} \to \mathbb{C}^{\times}$ . Then  $\operatorname{im} f \leq S$  is a subgroup where  $S_q := \{\omega_q^k \mid k \in \mathbb{Z}\}$  is the group of q-th roots of unity.

It is a fact from Algebra that  $S_q \cong (\mathbb{Z}/q\mathbb{Z})^{\times}$ , hence Dirichlet characters modulo a prime q are in 1-to-1 correspondence with the endomorphisms  $\operatorname{End}((\mathbb{Z}/q\mathbb{Z})^{\times})$  of  $(\mathbb{Z}/q\mathbb{Z})^{\times}$ .

*Proof.* We have that  $S_q = \{x \in \mathbb{C}^{\times} \mid x^{q-1} = 1\}$  and the claim directly follows from Corollary 12.

Note that the endomorphism monoid  $\operatorname{End}((\mathbb{Z}/q\mathbb{Z})^{\times})$  is not a group, except in the trivial case q=2. The reason is that e.g. the trivial group homomorphism  $r\mapsto 1$  is not surjective and thus not invertible.

**Definition 15.** Denote by Dir(q) the set of Dirichlet characters modulo q.

By Corollary 13 each group endomorphism  $f \in \operatorname{End}((\mathbb{Z}/q\mathbb{Z})^{\times})$  is determined by its value at a primitive root of unity  $r \in (\mathbb{Z}/q\mathbb{Z})^{\times}$ , hence

$$|\operatorname{Dir}(q)| = |\operatorname{End}((\mathbb{Z}/q\mathbb{Z})^{\times})| = |(\mathbb{Z}/q\mathbb{Z})^{\times}| = q - 1$$

It follows that there are exactly q-1 distinct Dirichlet characters modulo a prime q.

**Remark 16.** It is again a fact that  $(\mathbb{Z}/p^k\mathbb{Z})^{\times}$  is cyclic for an odd prime p and  $k \geq 1$ . Hence, everything up to now can also be done for odd prime powers, if we replace q-1 by  $\phi(q)$ .

Because of Lemma 5 it might seem like a good idea to study in which cases the value  $\sum_{x \in (\mathbb{Z}/q\mathbb{Z})^{\times}} \chi(x)$  is zero.

**Proposition 17** (Ex (iii)). Let  $\chi_0$  be the trivial Dirichlet character given by  $r \mapsto 1$ . Then

$$\sum_{a \in (\mathbb{Z}/q\mathbb{Z})^{\times}} \chi(a) = \begin{cases} q - 1 & \text{if } \chi = \chi_0 \\ 0 & \text{otherwise} \end{cases},$$

$$\sum_{\chi \in \text{Dir}(q)} \chi(a) = \begin{cases} q - 1 & \text{if } a \equiv 1 \mod q \\ 0 & \text{otherwise} \end{cases}$$

Furthermore, for  $b \perp q$  have

$$\sum_{\chi \in \text{Dir}(q)} \chi(a) \overline{\chi(b)} = \begin{cases} q - 1 & \text{if } a \equiv b \mod q \\ 0 & \text{otherwise} \end{cases}$$

*Proof.* Clearly

$$\sum_{a \in (\mathbb{Z}/q\mathbb{Z})^{\times}} \chi_0(a) = q - 1 \quad \text{and} \quad \sum_{\chi \in \text{Dir}(q)} \chi(1) = \sum_{\chi \in \text{Dir}(q)} 1 = q - 1$$

So it is left to show that we get zero in the other cases.

Consider a Dirichlet character  $\chi \neq \chi_0$  given by  $r \mapsto \xi$  for a q-th root of unity  $\xi \neq 1$ . Then

$$\sum_{a \in (\mathbb{Z}/q\mathbb{Z})^{\times}} \chi(a) = \sum_{k=0}^{q-2} \chi(r^k) = \sum_{k=0}^{q-2} \xi^k = \frac{1-\xi^{q-1}}{q-\xi} = 0$$

By using the earlier results on the structure of Dir(q) we see that for  $a \equiv r^k \not\equiv 1 \mod q$ , have

$$\sum_{\chi \in \text{Dir}(q)} \chi(a) = \sum_{\chi \in \text{Dir}(q)} \chi(r)^k$$

$$= \sum_{\xi \text{ q-th root of unity}} \xi^k = \sum_{l=0}^{q-2} \omega^{kl} = \frac{1 - (\omega^{q-1})^k}{1 - \omega^k} = 0$$

where  $\omega \in \mathbb{C}$  is a primitive q-th root of unity and  $r \in \mathbb{Z}$  is a primitive root modulo q.

For the last part, note that for any q-th root of unity  $\xi$ , we have  $\xi \overline{\xi} \in \mathbb{R}$  with  $\xi \overline{\xi} = |\xi|^2 > 0$ . Furthermore,  $\overline{\xi}$  is also a q-th root of unity, and so we see that  $\xi \overline{\xi} = 1$  (the only real, positive root of unity is 1). It follows that for any Dirichlet character  $\chi$  have  $\overline{\chi([a])} = \chi([a]^{-1})$ . Thus

$$\sum_{\chi \in \text{Dir}(q)} \chi(a) \overline{\chi(b)} = \sum_{\chi \in \text{Dir}(q)} \chi([a][b]^{-1}) = \begin{cases} q - 1 & \text{if } [a][b]^{-1} = 1 \in (\mathbb{Z}/q\mathbb{Z})^{\times} \\ 0 & \text{otherwise} \end{cases}$$

The condition  $ab^{-1} = 1$  is equivalent to  $a \equiv b \mod q$ , so the claim follows.

Using these basic results, we can now prove facts on the Dirichlet series of characters.

**Proposition 18** (Ex (iv)). Let  $a \perp q$ . Then for  $\Re(s) > 1$  have

$$\sum_{n\equiv a \mod q} \frac{\Lambda(n)}{n^s} = \frac{1}{q-1} \sum_{\chi \in \mathrm{Dir}(q)} \overline{\chi(a)} \sum_{n \geq 1} \frac{\Lambda(n)\chi(n)}{n^s}$$

(All those series obviously converge absolutely since  $\Re(s) > 1$ )

*Proof.* By Prop. 17 we have for all  $n \in \mathbb{N}$  that

$$\frac{1}{q-1} \sum_{\chi \in \text{Dir}(q)} \overline{\chi(a)} \chi(n) = \begin{cases} 1 & \text{if } a \equiv n \mod q \\ 0 & \text{otherwise} \end{cases}$$

It follows that

$$\begin{split} \sum_{n \equiv a \mod q} \Lambda(n) n^{-s} &= \sum_{n \geq 1} \Lambda(n) n^{-s} \begin{cases} 1 & \text{if } a \equiv n \mod q \\ 0 & \text{otherwise} \end{cases} \\ &= \sum_{n \geq 1} \Lambda(n) n^{-s} \frac{1}{q-1} \sum_{\chi \in \mathrm{Dir}(q)} \overline{\chi(a)} \chi(n) \\ &= \frac{1}{q-1} \sum_{\chi \in \mathrm{Dir}(q)} \overline{\chi(a)} \sum_{n \geq 1} \Lambda(n) \chi(n) n^{-s} \end{split}$$

as infinite summation clearly commutes with finite sums.

**Example 19** (Ex (v)). We consider the Dirichlet characters mod 5. A (primitive) 5-th root of unity  $\omega_5 \in \mathbb{C}$  is given by  $\omega_5 = \exp(2\pi i/5)$ . On the other hand, a primitive root modulo 5 is e.g. given by r = 2 since  $2^2 \equiv -1 \mod 5$ . Thus we have the trivial Dirichlet character  $\chi_0$  and 5 - 1 = 4 nontrivial Dirichlet characters mod 5, namely those given by

$$\chi_1: 1 \mapsto 1, \ 2 \mapsto \omega_5 = \exp(2\pi i/5), \ 3 \mapsto \omega_5^3 = \exp(6\pi i/5), \ 4 \mapsto \omega_5^2 = \exp(4\pi i/5), 
\chi_2: 1 \mapsto 1, \ 2 \mapsto \omega_5^2 = \exp(4\pi i/5), \ 3 \mapsto \omega_5 = \exp(2\pi i/5), \ 4 \mapsto \omega_5^4 = \exp(8\pi i/5), 
\chi_3: 1 \mapsto 1, \ 2 \mapsto \omega_5^3 = \exp(6\pi i/5), \ 3 \mapsto \omega_5^4 = \exp(8\pi i/5), \ 4 \mapsto \omega_5^1 = \exp(2\pi i/5), 
\chi_4: 1 \mapsto 1, \ 2 \mapsto \omega_5^4 = \exp(8\pi i/5), \ 3 \mapsto \omega_5^2 = \exp(4\pi i/5), \ 4 \mapsto \omega_5^3 = \exp(6\pi i/5), 
\chi_4: 1 \mapsto 1, \ 2 \mapsto \omega_5^4 = \exp(8\pi i/5), \ 3 \mapsto \omega_5^2 = \exp(4\pi i/5), \ 4 \mapsto \omega_5^3 = \exp(6\pi i/5),$$

## 3 Part III

Again, let  $q \geq 3$  be a prime. Let further  $\chi$  be a Dirichlet character mod q.

**Proposition 20** (Ex (i)). For  $\Re(s) > 1$  have that

$$\frac{L(s,\chi)'}{L(s,\chi)} = \sum_{n>1} \frac{\Lambda(n)\chi(n)}{n^s}$$

*Proof.* Consider any  $\epsilon > 0$ . The series

$$\sum_{n\geq 1} \frac{d}{ds} \chi(n) n^{-s} = \sum_{n\geq 1} \chi(n) \log(n) n^{-s}$$

converges uniformly on  $\Re(s) \geq 1 + \epsilon$ , as  $|\chi(n)| \leq C$  for some C > 0 and all  $n \in \mathbb{N}$  (by the lecture, we know that  $\sum_n \log(n) n^{-s}$  converges uniformly on  $\Re(s) \geq 1 + \epsilon$ ). Hence, we may interchange summation and differentiation to get

$$L(s,\chi)' = \sum_{n\geq 1} \chi(n) \frac{d}{ds} n^{-s} = \sum_{n\geq 1} \chi(n) \log(n) n^{-s}$$

for  $\Re(s) \ge 1 + \epsilon$ . As  $\epsilon > 0$  was arbitrary, we get

$$L(s,\chi)' = \sum_{n>1} \chi(n) \log(n) n^{-s}$$

for all  $\Re(s) > 1$ .

Furthermore,  $\chi$  and  $\mu$  are multiplicative, and hence so is  $(\chi \mu)(n) := \chi(n)\mu(n)$ . Thus we have the Euler products

$$\sum_{n \ge 1} \mu(n) \chi(n) n^{-s} = \prod_{p \in \mathbb{P}} \sum_{k \in \mathbb{N}} \mu(p^k) \chi(p^k) p^{-sk} = \prod_{p \in \mathbb{P}} (1 - \chi(p) p^{-s})$$

and

$$\sum_{n\geq 1} \chi(n) n^{-s} = \prod_{p\in \mathbb{P}} \sum_{k\in \mathbb{N}} \chi(p^k) p^{-sk} = \prod_{p\in \mathbb{P}} \frac{1}{1-\chi(p)p^{-s}}$$

Everything converges absolutely for  $\Re(s) > 1$ , and so it follows

$$\frac{1}{L(s,\chi)} = \sum_{n>1} (\chi \mu)(n) n^{-s}$$

By the compatibility of Dirichlet convolution and Dirichlet summation, we now find

$$L(s,\chi)'\frac{1}{L(s,\chi)} = \Bigl(\sum_{n \geq 1} \chi(n) \log(n) n^{-s}\Bigr) \Bigl(\sum_{n \geq 1} \chi(n) \mu(n) n^{-s}\Bigr) = \sum_{n \geq 1} (\chi \log * \chi \mu)(n) n^{-s}$$

and so it is left to show that  $\chi \log *\chi \mu = \chi \Lambda$ .

This is true, as for all  $n \in \mathbb{N}$  it holds

$$\begin{split} (\chi \log *\chi \mu)(n) &= \sum_{ab=n} \chi(a) \chi(b) \log(a) \mu(b) \\ &= \sum_{ab=n} \chi(ab) \log(a) \mu(b) = \chi(n) \sum_{ab=n} \log(a) \mu(b) \\ &= \chi(n) (\log *\mu)(n) = (\chi \Lambda)(n) \end{split}$$

Now we want to find an analytic continuation of  $L(s,\chi)$  to  $\Re(s) > 0$ . First of all, we consider  $\chi_0$ .

**Proposition 21** (Ex (ii)). For  $\Re(s) > 1$  we have

$$L(s, \chi_0) = (1 - q^{-s})\zeta(s)$$

In particular,  $L(s, \chi_0)$  has a meromorphic continuation to  $\Re(s) > 0$  with only one simple pole at s = 1.

*Proof.* As  $\chi_0$  is fully multiplicative, we have the Euler product

$$L(s,\chi_0) = \sum_{n\geq 1} \chi_0(n) n^{-s} = \prod_{p\in\mathbb{P}} \frac{1}{1-\chi_0(p)p^{-s}} = \prod_{p\neq q} \frac{1}{1-p^{-s}}$$
$$= (1-q^{-s}) \prod_{p\in\mathbb{P}} \frac{1}{1-p^{-s}} = (1-q^{-s})\zeta(s)$$

as all products converge absolutely.

For the other Dirichlet characters, the situation is slightly more complicated. First, we will bound the value of the partial sums of the Dirichlet series for  $0 < \Re(s) \le 1$ .

**Lemma 22.** Let  $\chi \neq \chi_0$  be a Dirichlet character mod q and consider the sum function

$$A(n) := \sum_{1 \le k \le n} \chi(k)$$

Then  $|A(n)| \leq q$  for all  $n \in \mathbb{N}$ .

*Proof.* Have

$$|A(n)| = \left| \sum_{1 \le k \le n} \chi(k) \right| \le \left| \sum_{q \lfloor n/q \rfloor < l \le n} \chi(l) \right| + \left| \sum_{0 \le k < \lfloor n/q \rfloor} \underbrace{\sum_{0 < l \le q} \chi(kq + l)}_{=0 \text{ by Prop. 17}}$$

$$= \left| \sum_{q \lfloor n/q \rfloor < l \le n} \chi(l) \right| \le \sum_{q \lfloor n/q \rfloor < l \le n} |\chi(l)| = \sum_{q \lfloor n/q \rfloor < l \le n} 1$$

$$= q(n/q - \lfloor n/q \rfloor) \le q$$

for all  $n \in \mathbb{N}$ .

**Lemma 23** (Ex (iii)). Let  $\chi \neq \chi_0$  be a Dirichlet character. Then for  $\Re(s) > 0$  have

$$\left| \sum_{1 \le n \le X} \chi(n) n^{-s} \right| \le q + \frac{q|s|}{\Re(s)} = O\left(\frac{q|s|}{\Re(s)}\right)$$

and in particular, this does not depend on X.

*Proof.* Using partial summation yields

$$\sum_{1 \le n \le X} \chi(n) n^{-s} = \sum_{1 - \epsilon < n \le X} \chi(n) n^{-s}$$

$$= \underbrace{A(1 - \epsilon)}_{=0} (1 - \epsilon)^{-s} - A(X) X^{-s} + s \int_{1 - \epsilon}^{X} A(t) t^{-(s+1)} dt$$

$$= -A(X) X^{-s} + s \int_{1}^{X} A(t) t^{-(s+1)} dt$$

So

$$\begin{split} \left| \sum_{1 \leq n \leq X} \chi(n) n^{-s} \right| &\leq |A(X)X^{-s}| + |s| \int_{1}^{X} |A(t)t^{-(s+1)}| dt \\ &\leq qX^{-\Re(s)} + |s| \int_{1}^{X} qt^{-\Re(s)-1} dt \\ &= qX^{-\Re(s)} + q|s| \left( \frac{1}{\Re(s)} - \frac{1}{X^{\Re(s)}\Re(s)} \right) \\ &\leq q + q \frac{|s|}{\Re(s)} = O\left( \frac{q|s|}{\Re(s)} \right) \end{split}$$

for 
$$\Re(s) > 0$$
.

Now we can show the analytic continuation of  $L(s,\chi)$  to  $\Re(s) > 0$ .

**Proposition 24** (Ex (iv)). Let  $\chi \neq \chi_0$  be a Dirichlet character mod q. Then

$$L(s,\chi) = s \int_{1}^{\infty} A(t)t^{-(s+1)}dt$$

for  $\Re(s) > 1$ . Further, the right-hand side is a holomorphic function on  $\Re(s) > 0$  and thus provides an analytic continuation of  $L(s,\chi)$  to  $\Re(s) > 0$ .

*Proof.* Similar to the proof of Lemma 23, partial summation yields

$$\sum_{n>1} \chi(n) n^{-s} = s \int_{1}^{\infty} A(t) t^{-(s+1)} dt$$

By Lemma 23, this is bounded and hence well-defined and finite for  $\Re(s) > 0$ . Further, the integral converges absolutely by Lemma 22, and thus is holomorphic on  $\Re(s) > 0$ .  $\square$ 

Corollary 25 (Ex (iv)). The function  $L(s,\chi)'/L(s,\chi)$  is bounded on a neighborhood of 1, provided that  $L(1,\chi) \neq 0$ .

*Proof.* As  $L(s,\chi)'/L(s,\chi)$  is meromorphic on  $\Re(s) > 0$ , we know that it is holomorphic on some neighborhood of 1 unless it has a pole at s = 1. In the third exercise class of ANT, it was shown that this would imply  $L(1,\chi) = 0$  or  $L(s,\chi)'$  has a pole at s = 1.

However, the derivative of a holomorphic function is again holomorphic, so  $L(s,\chi)'$  has no pole at s=1. Provided that  $L(1,\chi)\neq 0$ , it follows that  $L(s,\chi)'/L(s,\chi)$  is holomorphic on a compact neighborhood of 1, so bounded.

Now we can show the main result of this miniproject. We will prove two auxiliary lemmas before.

**Lemma 26.** For  $a \perp q$ , the function

$$\rho_a(s) := \frac{1}{q-1} \sum_{\chi \in \text{Dir}(q)} \overline{\chi(a)} \sum_{n \ge 1} \frac{\Lambda(n)\chi(n)}{n^s}$$

is a meromorphic function on  $\Re(s) > 0$  with a simple poles at 1 (and possibly other poles on  $\Re(s) > 0$ ).

*Proof.* By Prop. 20, we have for  $\chi \in \text{Dir}(q)$  that

$$\frac{\overline{\chi(a)}}{q-1} \sum_{n>1} \frac{\Lambda(n)\chi(n)}{n^s} = \frac{\overline{\chi(a)}}{q-1} \frac{L(s,\chi)'}{L(s,\chi)}$$

If  $\chi \neq \chi_0$ , then Corollary 25 shows that this function has no pole at s=1. If  $\chi = \chi_0$  on the other hand, Prop. 21 shows that

$$L(s, \chi_0) = (1 - q^{-s})\zeta(s)$$

Hence

$$\frac{L(s,\chi_0)'}{L(s,\chi_0)} = \frac{\log(q)q^{-s}\zeta(s) + (1-q^{-s})\zeta'(s)}{(1-q^{-s})\zeta(s)} = \frac{\log(q)}{q^s - 1} + \frac{\zeta'(s)}{\zeta(s)}$$

has a simple pole at s=1. Since  $a\perp q$ , we see that  $\chi_0(a)=1$  and thus also

$$\frac{\overline{\chi_0(a)}}{q-1} \sum_{n \ge 1} \frac{\Lambda(n)\chi_0(n)}{n^s} = \frac{\overline{\chi_0(a)}}{q-1} \frac{L(s,\chi_0)'}{L(s,\chi_0)}$$

has a simple pole at s = 1.

Together, this yields that the sum of those functions

$$\rho_a(s) = \frac{1}{q-1} \sum_{\chi \in \text{Dir}(q)} \overline{\chi(a)} \sum_{n \ge 1} \frac{\Lambda(n)\chi(n)}{n^s}$$

is a meromorphic function with a simple pole at s = 1.

**Lemma 27.** Let  $a \perp q$  and define

$$\Psi_a(x) := \sum_{n < x, \ n \equiv a \mod q} \Lambda(n)$$

and

$$\theta_a(x) := \sum_{p < x, \ p \equiv a \mod a} \log(p)$$

Then

$$\Psi_a(x) - \theta_a(x) = O(x^{1/2}\log(x))$$

*Proof.* Have

$$\begin{split} \Psi_{a}(x) - \theta_{a}(x) &= \sum_{p^{k} < x, \ p^{k} \equiv a \mod q} \log(p) - \sum_{p < x, \ p \equiv a \mod q} \log(p) \\ &= \sum_{p^{k} < x, \ k \ge 2, \ p^{k} \equiv a \mod q} \log(p) \le \sum_{p^{k} < x, \ k \ge 2} \log(p) \\ &= \Psi(x) - \theta(x) = O(x^{1/2} \log(x)) \end{split}$$

where the last equality was proven in the lecture.

**Proposition 28** (Ex (v)). Assume that  $L(1,\chi) \neq 0$  for all  $\chi \in \text{Dir}(q) \setminus \{\chi_0\}$ . Then for all  $a \perp q$  there are infinitely many primes  $p \equiv a \mod q$ .

*Proof.* Assume not, then  $\theta_a(x)$  is bounded, i.e.  $\theta_a(x) = O(1)$ . With Lemma 27 it follows that  $\Psi_a(x) = O(x^{1/2} \log x)$ .

By Prop. 18 we have that for  $\Re(s) > 1$ 

$$\rho_a(s) = \sum_{n \equiv a \mod q} \Lambda(n) n^{-s}$$

Partial summation yields that for  $\Re(s) > 1$  have

$$\begin{split} \rho_{a}(s) &= \sum_{n \equiv a \mod q} \Lambda(n) n^{-s} \\ &= \lim_{t \to \infty} \left( t^{-s} \sum_{n < t, \ n \equiv a \mod q} \Lambda(n) \right) + s \int_{1}^{\infty} \left( \sum_{n < t, \ n \equiv a \mod q} \Lambda(n) \right) t^{-(s+1)} dt \\ &= t^{-s} \Psi_{a}(t) = t^{-s} O(t \log t) = o(1) \\ &= s \int_{1}^{\infty} \Psi_{a}(t) t^{-s-1} dt = s \int_{1}^{\infty} O(t^{1/2} \log t) t^{-s-1} dt \\ &= O\left( |s| \int_{1}^{\infty} \log(t) t^{-\Re(s) - 1/2} dt \right) \\ &= O\left( |s| \left( \frac{1}{1/2 - \Re(s)} 1^{1/2 - \Re(s)} + \frac{1}{1/2 - \Re(s)} \int_{1}^{\infty} t^{-\Re(s) - 1/2} dt \right) \right) \\ &= O\left( |s| \frac{1}{(1/2 - \Re(s))^{2}} \right) \end{split}$$

However this function has no pole at s = 1, a contradiction to Lemma 26.

**Example 29** (Ex (vi)). For all the nontrivial Dirichlet characters  $\chi_1, ..., \chi_4$  defined in Example 19, we have

$$L(1,\chi_i) \neq 0$$

It follows that there are infinitely many primes  $\equiv a \mod 5$ , for all  $a \perp 5$ .

*Proof.* By Prop. 5 we know that

$$L(1,\chi_i) = \sum_{n \ge 1} \chi(n) n^{-s}$$

For the fifth root of unity  $\omega \in \mathbb{C}$  such that  $\chi_i(1) = \omega$ , we thus find

$$L(1,\chi_i) = \sum_{k\geq 0} \sum_{1\leq n\leq 4} \frac{\chi(5k+n)}{(5k+n)^s} = \sum_{k\geq 0} \frac{\omega}{(5k+1)^s} + \frac{\omega^2}{(5k+2)^s} + \frac{\omega^3}{(5k+3)^s} + \frac{\omega^4}{(5k+4)^s}$$
$$= \sum_{k\geq 0} \omega \left(\underbrace{\frac{1}{(5k+1)^s} - \frac{1}{(5k+4)^s}}_{>0}\right) + \omega^2 \left(\underbrace{\frac{1}{(5k+2)^s} - \frac{1}{(5k+3)^s}}_{>0}\right)$$

Hence we have positive coefficients  $a_k, b_k > 0$  with

$$L(1,\chi_i) - \sum_{k \ge 0} a_k \omega + b_k \omega^2 = \omega \sum_{k \ge 0} a_k + b_k \omega$$

In particular,

$$\Im\left(\frac{L(1,\chi_i)}{\omega}\right) = \sum_{k\geq 0} b_k \Im(\omega) = \Im(\omega) \underbrace{\sum_{k\geq 0} b_k}_{>0}$$

Since  $\chi_i$  is a nontrivial Dirichlet character, we see that  $\Im(\omega) \neq 0$  and so  $\Im(L(1,\chi_i)/\omega) \neq 0$ , thus  $L(1,\chi_i) \neq 0$ .

Remark 30 (Ex (vii)). TODO
